Conceptual overview of pair-based classification and the role of RLR

RLR keeps the pair-based representation, but changes candidate refinement, encoding, and aggregation.

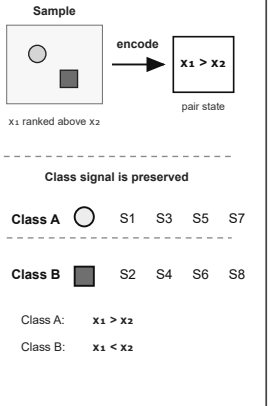

A. Value space

Cohort shifts alter amplitudes

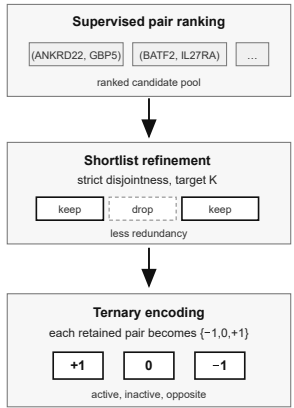

B. Relational space

Order is more stable than scale

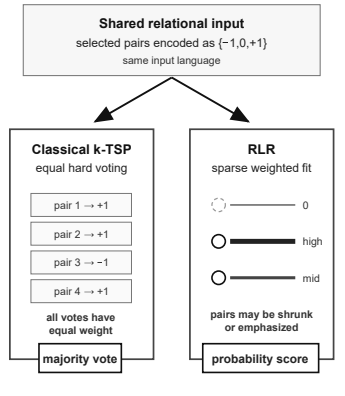

C. Pair-signature construction

RLR uses more than "top pairs only"

D. Aggregation stage

The key difference is how pairs are combined

Value space may drift across cohorts, whereas pair relations define a more stable representation; RLR then differs from classical k-TSP mainly in refinement and aggregation.
